

Native steady 3D Navier-Stokes in an ordinary tanh MLP

Forcing and prescribed boundary velocity only; no interior solution data or external PDE trajectory.

$N = 129$ at $p = 4$, then $N = 257$. Final: 84,099 tanh neurons; 3,876 solved coordinates.

Final audit: 2,048 values and 1,024 derivative points, plus corners and wall checks.

Sequential native continuation; settings change between stages. This is not a controlled scaling-law fit.
